## Abstract of JP10174185

**PROBLEM TO BE SOLVED:** To minimize data avoided undesirably due to mismatching between a transmission speed and a buffer capacity and invalid data losing real time performance. **SOLUTION:** A host station 1 designates an outgoing control physical channel structure to a radio base station 3 at the start system operation. The radio base station 3 obtains an optimum buffer capacity  $C_s$  according to an equation  $C_s = V_s \times T_e$ , where  $V_s$  is a transmission speed in each function channel depending on a designated control physical channel structure and  $T_e$  is a time a reply wait time of a host station 1 from a mobile equipment 5 with some margin. Since the buffer capacity is selected in this way, data invalidated not in time for a reply wait of the host station 1 in a consecutive high load state are aborted before being stored in the buffer. Thus, the data sent to the mobile equipment 5 actually are all validated and then the transmission capability of a radio channel is utilized efficiently.
